2.9 C8.4: Probabilistic Combinatorics - 16 HT 13
3 Mathematics units 16

SC7 Bayes Methods isn’t being offered this year.

Every effort is made to ensure that the list of courses offered is accurate at the time of going online. However, students are advised to check the up-to-date version of this document on the Department of Statistics website.

Notice of misprints or errors of any kind, and suggestions for improvements in this booklet should be addressed to the Academic Administrator in the Department of Statistics, academic.administrator@stats.ox.ac.uk.

Updated August 2021
1 Honour School of Mathematics and Statistics

1.1 Units

See the current edition of the Examination Regulations at https://examregs.admin.ox.ac.uk for the full regulations governing these examinations. The examination conventions can be found at Canvas Mathematics and Statistics Part C Examinations and Assessments.

In Part C,

- each candidate shall offer a minimum of six units and a maximum of eight units from the schedule of units for Part C
- and each candidate shall also offer a dissertation on a statistics project (equivalent of 2 units).

At least two units should be from the schedule of ‘Statistics’ units. The USMs for the dissertation and the best six units will count for the final classification.

Units from the schedule of ‘Mathematics Department units’ for Part C of the Honour School of Mathematics are also available – see Section 3.

This booklet describes the units available in Part C. Information about dissertations/statistics projects will be available on the Department of Statistics Canvas site.

All of the units described in this booklet are “M-level”.

Students are asked to register for the options they intend to take by the end of week 10, Trinity Term 2021 using the Mathematical Institute course management portal. https://courses.maths.ox.ac.uk/. Students may alter the options they have registered for after this but it is helpful if their registration is as accurate as possible. Students will then be asked to sign up for classes at the start of Michaelmas Term 2021. Students who register for a course or courses for which there is a quota should consider registering for an additional course (by way of a "reserve choice") in case they do not receive a place on the course with the quota.

Every effort will be made when timetabling lectures to ensure that mathematics lectures do not clash. However, because of the large number of options this may sometimes be unavoidable.

1.2 Part C courses in future years

In any year, most courses available in Part C that year will normally also be available in Part C the following year. However, sometimes new options will be added or existing options may cease to run. The list of courses that will be available in Part C in any year will be published by the end of the preceding Trinity Term.
1.3 Course list by term

The 2021-2022 list of Part C courses by term is:

Michaelmas Term

SC1 Stochastic Models in Mathematical Genetics
SC2 Probability and Statistics for Network Analysis
SC6 Graphical Models
SC9 Probability on Graphs and Lattices

Hilary Term

SC4 Advanced Topics in Statistical Machine Learning
SC5 Advanced Simulation Methods
SC8 Topics in Computational Biology
SC10 Algorithmic Foundations of Learning
C8.4 Probabilistic Combinatorics.
2. Statistics Units

2.1 SC1 Stochastic Models in Mathematical Genetics – 16 MT

Level: M-level
Method of Assessment: written examination
Weight: Unit

Recommended Prerequisites
Part A A8 Probability.
SB3.1 Applied Probability would be helpful.

Aims & Objectives
The aim of the lectures is to introduce modern stochastic models in mathematical population genetics and give examples of real world applications of these models. Stochastic and graph theoretic properties of coalescent and genealogical trees are studied in the first eight lectures. Diffusion processes and extensions to model additional key biological phenomena are studied in the second eight lectures.

Synopsis
Evolutionary models in Mathematical Genetics:

The Coalescent process describing the stochastic behaviour of the ancestral tree of a collection of DNA sequences. Mutations on ancestral lineages in a coalescent tree. Models with a variable population size.

The frequency spectrum and age of a mutation. Ewens' sampling formula for the probability distribution of the allele configuration of DNA sequences in a sample in the infinitely-many-alleles model. Hoppe’s urn model for the infinitely-many-alleles model.

The infinitely-many-sites model of mutations on DNA sequences. Gene trees as perfect phylogenies describing the mutation history of a sample of DNA sequences. Graph theoretic constructions and characterizations of gene trees from DNA sequence variation. Gusfield’s construction algorithm of a tree from DNA sequences. Examples of gene trees from data.

Reading

2.2 **SC2 Probability and Statistics for Network Analysis** – 16 MT

Level: M-level
Method of Assessment: Written examination
Weight: Unit

For this course, 2 lectures and 2 intercollegiate classes are replaced by 2 practical classes. (The total time for this course is the same as for other Part C courses.)

*Recommended prerequisites*
Part A A8 Probability and A9 Statistics

*Aims and Objectives*
Many data come in the form of networks, for example friendship data and protein-protein interaction data. As the data usually cannot be modelled using simple independence assumptions, their statistical analysis provides many challenges. The course will give an introduction to the main problems and the main statistical techniques used in this field. The techniques are applicable to a wide range of complex problems. The statistical analysis benefits from insights which stem from probabilistic modelling, and the course will combine both aspects.

*Synopsis*

Probabilistic models: Bernoulli random graphs, geometric random graphs, preferential attachment models, small world networks, inhomogeneous random graphs, exponential random graphs.

Small subgraphs: Stein’s method for normal and Poisson approximation. Branching process approximations, threshold behaviour, shortest path between two vertices.

*Reading*
2.3 **SC4 Advanced Topics in Statistical Machine Learning** – 16 HT

**Level:** M-level  
**Methods of Assessment:** written examination.  
**Weight:** Unit

**Recommended prerequisites**  
The course requires a good level of mathematical maturity. Students are expected to be familiar with core concepts in statistics (regression models, bias-variance tradeoff, Bayesian inference), probability (multivariate distributions, conditioning) and linear algebra (matrix-vector operations, eigenvalues and eigenvectors). Previous exposure to machine learning (empirical risk minimisation, dimensionality reduction, overfitting, regularisation) is highly recommended. Students would also benefit from being familiar with the material covered in the following courses offered in the Statistics department: SB2.1 (formerly SB2a) Foundations of Statistical Inference and in SB2.2 (formerly SB2b) Statistical Machine Learning.

**Aims and Objectives**  
Machine learning is widely used across the sciences, engineering and society, to construct methods for identifying interesting patterns and predicting accurately from large datasets. This course introduces several widely used machine learning techniques and describes their underpinning statistical principles and properties. The course studies both unsupervised and supervised learning and several advanced and state-of-the-art topics are covered in detail. The course will also cover computational considerations of machine learning algorithms and how they can scale to large datasets.

**Synopsis**  

Support vector machines.

Kernel methods and reproducing kernel Hilbert spaces. Representer theorem. Representation of probabilities in RKHS.

Gaussian processes. Bayesian optimisation.
Software
Knowledge of Python is not required for this course, but some examples may be done in Python. Students interested in learning Python are referred to the following free University IT online course, which should ideally be taken before the beginning of this course: https://skills.it.ox.ac.uk/whats-on#/course/LY046

2.4 SC5 Advanced Simulation Methods - 16 HT

Level: M-level
Methods of Assessment: This course is assessed by written examination.
Weight: Unit

Recommended Prerequisites
The course requires a good level of mathematical maturity as well as some statistical intuition and background knowledge to motivate the course. Students are expected to be familiar with core concepts from probability (conditional probability, conditional densities, properties of conditional expectations, basic inequalities such as Markov’s, Chebyshev’s and Cauchy-Schwarz’s, modes of convergence), basic limit theorems from probability in particular the strong law of large numbers and the central limit theorem, Markov chains, aperiodicity, irreducibility, stationary distributions, reversibility and convergence. Most of these concepts are covered in courses offered in the Statistics department, in particular prelims probability, A8 probability and SB3.1 (formerly SB3a) Applied Probability. Familiarity with basic Monte Carlo methods will be helpful, as for example covered in A12 Simulation and Statistical Programming. Some familiarity with concepts from Bayesian inference such as posterior distributions will be useful in order to understand the motivation behind the material of the course.

Aims and Objectives
The aim of the lectures is to introduce modern simulation methods. This course concentrates on Markov chain Monte Carlo (MCMC) methods and Sequential Monte Carlo (SMC) methods. Examples of applications of these methods to complex inference problems will be given.

Synopsis
Classical methods: inversion, rejection, composition.

Importance sampling.

Advanced MCMC methods: Gibbs sampling, slice sampling, tempering/annealing, Hamiltonian (or Hybrid) Monte Carlo, pseudo-marginal MCMC.

Sequential importance sampling.

SMC methods: nonlinear filtering.

Reading

Further reading

2.5 **SC6 Graphical Models** – 16 MT

Level: M-level
Method of Assessment: Written examination
Weight: Unit

**Recommended Prerequisites**
The basics of Markov chains (in particular, conditional independence) from Part A Probability is assumed. Likelihood theory, contingency tables, and likelihood-ratio tests are also important; this is covered in Part A Statistics. Knowledge of exponential families and linear models, as covered in SB2.1 (formerly SB2a) Foundations of Statistical Inference and SB1.1 (formerly SB1a) Applied Statistics, would be useful, but is not essential.

**Aims and Objectives**
This course will give an overview of the use of graphical models as a tool for statistical inference. Graphical models relate the structure of a graph to the structure of a multivariate probability distribution, usually via a factorisation of the distribution or conditional independence constraints.

This has two broad uses: first, conditional independence can provide vast savings in computational effort, both in terms of the representation of large multivariate models and in performing inference with them; this makes graphical models very popular for dealing with big data problems. Second, conditional independence can be used as a tool to discover hidden structure in data, such as that relating to the direction of causality or to unobserved processes. As such, graphical models are widely used in genetics, medicine, epidemiology, statistical physics, economics, the social sciences and elsewhere.

Students will develop an understanding of the use of conditional independence and graphical structures for dealing with multivariate statistical models. They will appreciate how this is applied to causal modelling, and to computation in large-scale statistical problems.

**Synopsis**
Independence, conditional independence, graphoid axioms
Exponential families, mean and canonical parameterisations, moment
matching: contingency tables, log-linear models.
Undirected graphs, cliques, paths; factorisation and Markov properties, Hammersley-
Clifford Theorem (statement only)
Trees, cycles, chords, decomposability, triangulation. Maximum likelihood in
decomposable models, iterative proportional fitting.
The multivariate Gaussian distribution and Gaussian graphical models.
Directed acyclic graphs, factorisation. Paths, d-separation, moralisation. Ancestral sets
and sub-models. Decomposable models as intersection of directed and undirected
models.
Running intersection property, Junction trees; message passing, computation of
marginal and conditional probabilities, introduction of evidence
Causal models, structural equations, interventions, constraint-based learning,
faithfulness. The trek rule and back-door adjustment. Optimal adjustment sets.

2.7 SC8 Topics in Computational Biology – 16 HT

Level: M-level
Method of Assessment: Mini-project
Weight: Unit

Recommended Prerequisites:
The lectures attempt to be self-contained but clearly knowledge algorithms,
combinatorics and probability theory (A8 Probability and SB3.1 Applied Probability)
would be a help. The course requires a good level of mathematical maturity.

Aims & Objectives
Modern molecular biology generates large amounts of data, such as sequences,
structures and expression data, that needs different forms of statistical analysis and
modelling to be properly interpreted. This course focuses on four topics within this vast
area: Molecular Dynamics, Molecule Enumeration, Comparative Biology and Overview
of Computational Biology and Computational Neurosciences.

Synopsis:
Computational Neuroscience - Computational Neuroscience is in massive growth, but
has a history going back to the 1940s with publications like McCullogh and Pitts (1943)
paper on neural networks. The present progress is driven by progress on three fronts: (i)
Experimental data on brains, nerve systems and individual neurons, (ii) increased success in designing artificial neural networks with an increasing variety in architectures with applications in Deep Learning/AI and (iii) the ability to simulate very complex models as models of biological neural networks.

Neuroscience and Computational Neuroscience are arguably the most complex areas of present science it could take many decades for the most fundamental questions to be answered. The origin(s) of Neurosystems (and general likelihood/unlikelihood) is still an open question. The definition of consciousness is not only a philosophical question but of practical importance.

**Machine Learning in the Biosciences** - Machine Learning [ML] and Deep Learning [DL] have proved very powerful in the Biosciences. ML/DL is now a vast topic with a lot of architectures [recurrent, convolutional, autoencoder, generative adversarial networks (GANs),... ] design to model different problems. There are a large set of learning algorithm making these architectures fit/analyse large data sets. Deep Learning methods is getting a lot of attention with the latest success prediction of protein structure but has also proven useful in other areas of structural biology, such as prediction of physical contacts and function, as well as RNA analysis. Other success areas are Chemoinformatics and Genomics. In chemoinformatics, Graph Convolutional Networks have been especially useful and the problems of key interest include property prediction of small molecules [annotation of chemical space], reactions and catalysis. In Genomics prediction of expression levels, phenotypes associated a genome and annotation of genomes are recent success areas for ML/DL.

**Computational Virology** - Viruses are fascinating biological entities and there is a huge interest in them and much of the research is turning Computational. We will give an overview of viruses - the genomes, structure, classification and mode of reproduction. Models of virus spread from very basic models without spatial structure to more complicated models will be presented. Molecular evolution of viruses spans from years to possibly millennia; in principle to 3 billion years but viral evolution is so fast that inference of their evolution can only go a fraction of that back in time. Evolutionary studies shed light on rate, functional constraints and appearance of malignancy. Evolution within an individual illuminate the tug of war between immune system and the virus. This topic was introduced in 2021 and proved a prescient choice. This was taken as an opportunity and SARS-CoV-2/COVID-19 was taken as a case study in these lectures and the associate Class Discussions.

**Modelling the Biosphere** - The biosphere is a well-defined physical system that can be described at different levels of coarse-grained. At the most detailed level, it is an extremely complicated system with an energy in- and outflux, a physical system consisting of atmosphere, ocean and crust and in excess of 10 million species. But even at the very coarsest level major insights can be obtained and the greenhouse effect was pretty precisely described 130 years based on the simplest of models. Climate Change and Weather Forecasting make models of immense economic importance and are experience major development, both in terms of data collection, parameterisation and computational power. Like in epidemics, forecasting and assessment of forecasting is important. Statistical testing and causal analysis of biospheric changes are also receiving major attention. Describing scenarios of Climate Change is of interest to all and the foundation of political and economic decision making.
The exact plan for lectures is:

W1  Biological & Artificial Neurons
W1  Modelling Small Neural Networks
W2  Large Scale Brain Modelling
W2  Evolution of the Brain
W3  Basics of Machine and Deep Learning
W3  Applications in Structural Biology
W4  Applications in Chemoinformatics
W4  Applications in Genomics
W5  The Basics of Virology and Epidemics
W5  Molecular Evolution of Viruses
W6  Spread of Viral Epidemics
W6  Intra-Host Evolution of Viruses
W7  The Basics of the Biosphere
W7  Modelling the Dynamics of the Biosphere
W8  Short- and Long-Term Forecasting of the Biosphere
W8  Climate Change

Further Reading

2.8  SC9 Probability on Graphs and Lattices – 16 MT

Level: M-level
Method of Assessment: Written examination
Weight:  Unit

Recommended Prerequisites
Discrete and continuous time Markov process on countable state space, as covered for example in Part A A8 Probability and Part B SB3.1 (formerly SB3a) Applied Probability.

Aims and Objectives
The aim is to introduce fundamental probabilistic and combinatorial tools, as well as key models, in the theory of discrete disordered systems. We will examine the large-scale behaviour of systems containing many interacting components, subject to some random noise. Models of this type have a wealth of applications in statistical physics, biology and beyond, and we will see several key examples in the course. Many of the tools we will discuss are also of independent theoretical interest, and have far reaching applications.
For example, we will study the amount of time it takes for this process to reach the stationary distribution (mixing time). This concept is also important in many statistical applications, such as studying the run time of MCMC methods.

**Synopsis**
- Percolation and phase transitions.
- Uniform spanning trees, loop-erased random walks, and Wilson's algorithm.
- Important models: Stochastic Ising model (Glauber dynamics), Random-cluster model, Contact process, Exclusion process, Hard-core model.
- Important tools: Monotonicity, coupling, duality, FKG inequality.
- Gibbs measures and a discussion of phase transitions in this context.
- Mixing times and the spectral gap.

**Reading**
H. Duminil-Copin, *Introduction to Bernoulli percolation*. These are a set of notes from 2017, which are easily available online.

### 2.9 SC10 Algorithmic Foundations of Learning – 16 HT

**Level:** M-level  
**Method of Assessment:** Written examination  
**Weight:** Unit

**Recommended Prerequisites**
The course requires a good level of mathematical maturity. Students are expected to have working knowledge of core concepts in probability theory (basic properties of probabilities, such as union bounds, and of conditional expectations, such as the tower property or law of total expectations; basic inequalities, such as Markov’s and Jensen’s), statistics (confidence intervals, hypothesis testing), and linear algebra (matrix-vector operations, eigenvalues and eigenvectors; basic inequalities, such as Cauchy-Schwarz’s and Hölder’s). Previous exposure to machine learning (empirical risk minimisation, overfitting, regularisation) is recommended.

Students would benefit from being familiar with the material covered in SB2.1 (formerly SB2a) Foundations of Statistical Inference (in particular, Decision Theory) and in SB2.2 (formerly SB2b) Statistical Machine Learning.
Aims and objectives
The course is meant to provide a rigorous theoretical account of the main ideas underlying machine learning, and to offer a principled framework to understand the algorithmic paradigms being used, along with non-asymptotic methods for the study of random structures in high-dimensional probability, statistics, and optimisation.

Synopsis

- Statistical learning frameworks for prediction, estimation and online learning.
  - Probability:
    - Maximal inequalities.
    - Rademacher and Gaussian complexities.
    - Elements of VC theory.
    - Covering and packing numbers.
    - Chaining.
    - Concentration inequalities.
  - Statistics:
    - Bayes decision rules.
    - Learning via uniform convergence, margin bounds, and algorithmic stability.
    - Regularisation: explicit (constraints and penalisation) and implicit (algorithmic).
    - Convex loss surrogates.
    - Slow and fast rates.
    - Minimax lower bounds and hypothesis testing.
  - Optimisation:
    - Elements of convex theory.
    - Implicit Bias.
    - Online optimisation.
- Examples
  - Linear predictors, including Boosting.
  - Non-linear predictors, including Support Vector Machines and Neural Networks.
  - High-dimensional estimators for sparse and low-rank problems, including Lasso.
  - Online learning, including multi-armed bandit problems, reinforcement learning and algorithms.

2.95  **C8.4 Probabilistic Combinatorics** - 16 HT

Level: M-level
Method of Assessment: Written examination.
Weight: Unit

*Recommended Prerequisites:*
Part B Graph Theory and Part A A8 Probability. C8.3 Combinatorics is not an essential prerequisite for this course, though it is a natural companion for it.

*Overview*
Probabilistic combinatorics is a very active field of mathematics, with connections to other areas such as computer science and statistical physics. Probabilistic methods are essential for the study of random discrete structures and for the analysis of algorithms, but they can also provide a powerful and beautiful approach for answering deterministic questions. The aim of this course is to introduce some fundamental probabilistic tools and present a few applications.

*Learning Outcomes*
The student will have developed an appreciation of probabilistic methods in discrete mathematics.

*Synopsis*
First-moment method, with applications to Ramsey numbers, and to graphs of high girth and high chromatic number.
Second-moment method, threshold functions for random graphs.
Lovász Local Lemma, with applications to two-colourings of hypergraphs, and to Ramsey numbers.
Chernoff bounds, concentration of measure, Janson’s inequality.
Branching processes and the phase transition in random graphs.
Clique and chromatic numbers of random graphs.
